### Referencing within evolving hypertext

Victor Grishchenko, J. A. Pouwelse, and Henk Sips

Delft University of Technology Mekelweg 4, 2628CD Delft, The Netherlands victor.grishchenko@gnail.com

Abstract. The classic hypertext model omits the process of text growth, evolution and synthesis. With hypertext creation becoming increasingly collaborative and change timescales becoming shorter, explicitly addressing text evolution is the key to the next stage of hypertext development. Uniform Resource Identifier (URI) is a proven general concept that enabled the Web. In application to versioned deep hypertext, expressive power of a classical hyperlink becomes insufficient.

Based on the Causal Trees model, we introduce a minimalistic but powerful query language of specifiers that provides us great flexibility of referencing within a changing hypertext. Specifiers capture the state of the text, point at changes, expose authorship or blend branches. Being a part of an URI, a specifier puts advanced distributed revision control techniques within reach of a regular web user.

### 1 Introduction

In the WWW/HTML model and, generally, in "chunked hypertext" systems the main addressable unit is a "page" which might optionally also have addressable "anchors" inside it. That is generally sufficient as long as we deal with static texts, albeit the requirement that a page author must pre-provision anchors is limiting. However, if we follow the general vision of a text as an evolving entity (the "wiki model"), then the expressive power of a classical hyperlink is insufficient. Since the addressed text is continuously changing, anchors might disappear, and the content that is actually addressed by the link might be reedited or its surroundings may change. Similarly, there is no standard way of pointing at particular statements and passages in the text. For collaboratively created texts, such a possibility is desirable. Also, there is no semantics in place to address co-existing versions of a text (named "branches" in the version control parlance). Those might be drafts, reeditions, alternative versions. Thus, our mission is to explore possible approaches and conventions of referencing particular parts of text, its particular versions, or both. We want to measure, mark and cut text in breadth and depth!

This paper is structured as follows. First, we consider relevant existing models and their limitations in Section 2. Section 3 briefly describes the Causal Trees (ct) model of text versioning and the basic primitives available for text/version

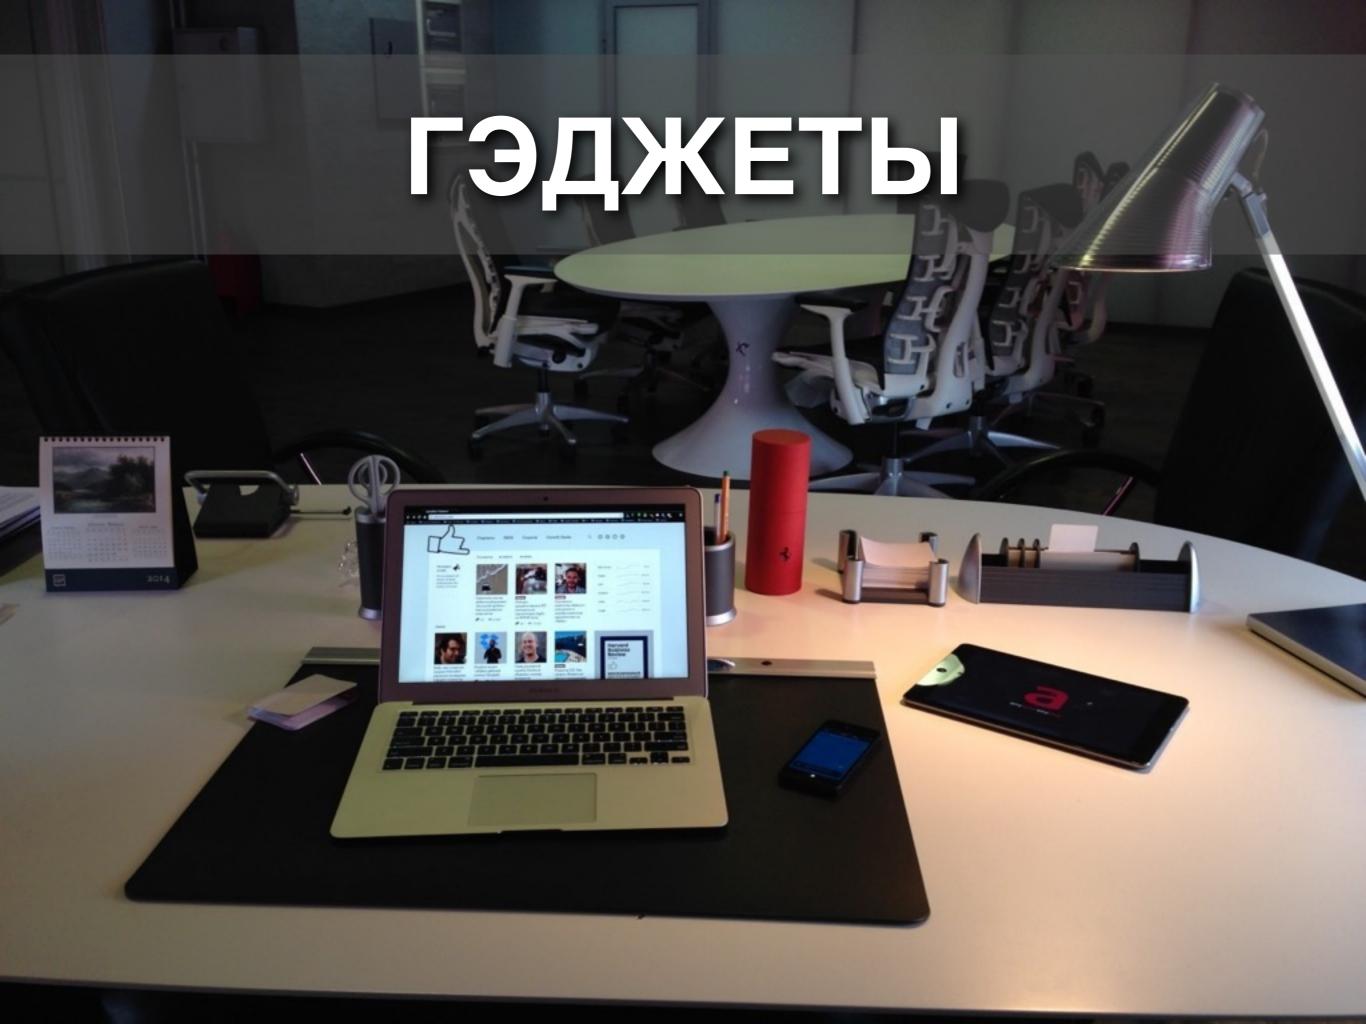

### Citrea and Swarm: partially ordered op logs in the browser

Victor Grishchenko Citrea LLC victor.grishchenko@gmail.com

25 March 2014

### Abstract

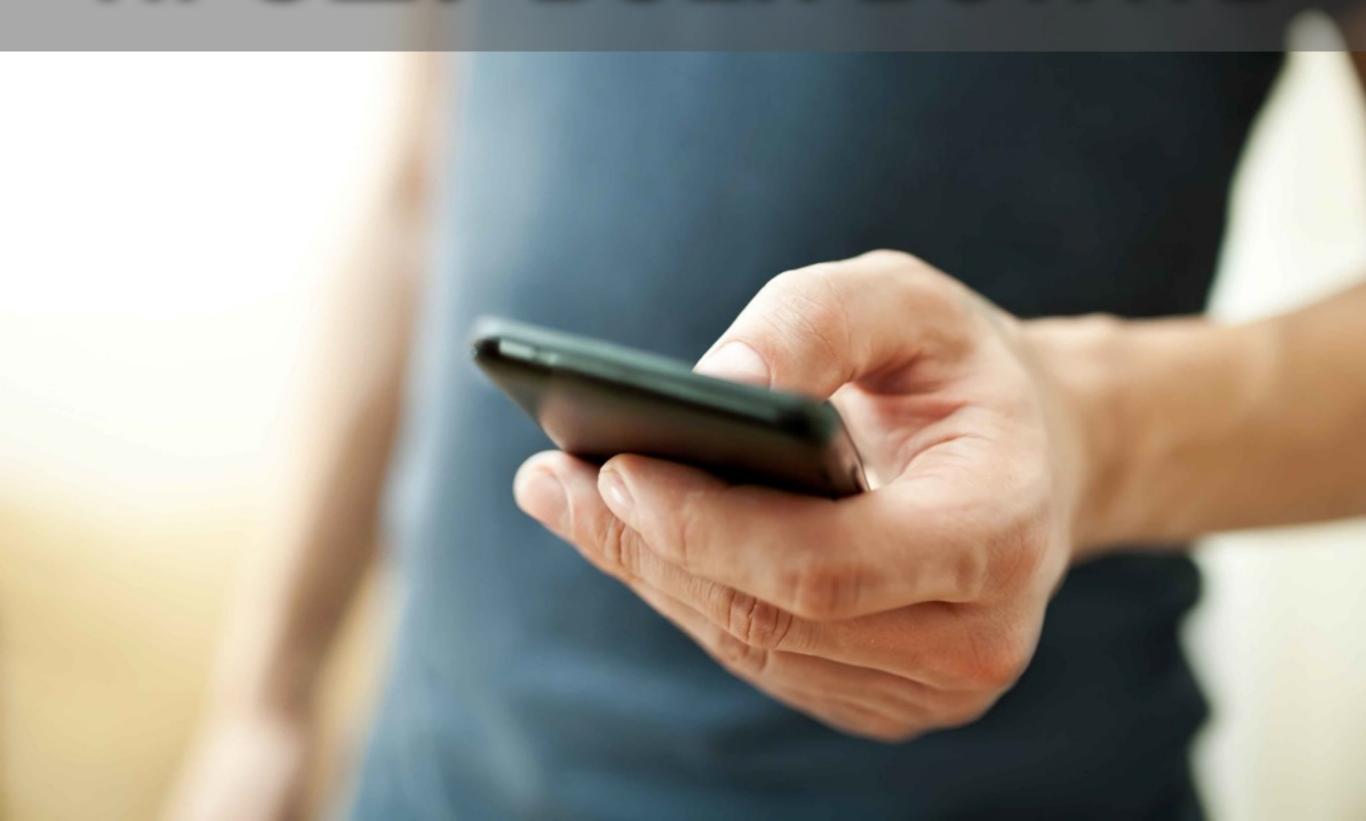

Principles of eventual consistency are normally applied in largescale distributed systems. I report experiences applying EC in Web app development. Citrea is a collaborative rich text editor employing the Causal Trees[4] technology of concurrency/version control (note: CT is not an OT flavor). CT employs symbol ids and trees and, generally, belongs to the same family as WOOT, Logoot or Treedoc [1, 3, 2]. CT makes the ids-and-trees approach production-practical by limiting itself to simple and lightweight algorithms and data structures. Swarm is a JavaScript object sync library that works in the browser, in real time. Swarm fully employs client-side storage and works well under intermittent connectivity. Swarm employs "pure" op-based model. Our top finding is a specifier, a serialized event description format that
